Disclosure

These slides were developed by Incyte Corporation (Wilmington, DE) from an interview with Kim-Hien Dao, DO, PhD, conducted in July 2015. Dr Dao has served as a consultant for Incyte Corporation and was compensated for her participation.

Introduction to polycythemia vera (PV)

- PV is a chronic clonal myeloproliferative neoplasm characterized by increased red cell mass¹
- Elevated white blood cell and platelet counts are also common¹

Reference: 1. Spivak JL. *Blood*. 2002;100(13):4272-4290.

Polycythemia vera may be indolent or aggressive

- Patients may live for decades, but studies have defined a subset of patients with PV with a much lower median survival rate, estimated at 5.8 years¹
- This is consistent with the median survival in primary myelofibrosis²

Risk-stratified survival that considers karyotype in 631 patients with PV.
PV, polycythemia vera.

Conventional factors to distinguish high-risk polycythemia vera

- The current rule of thumb is that patients aged <60 years who have no history of thrombosis are “low risk”¹
- This stratification is designed to estimate the likelihood of thrombotic complications in PV, but not disease progression or survival¹
- However, there are many other possible indications that PV may be high risk²
- These indicators of inadequately controlled, high-risk disease are not confined to any one phase of treatment and may occur at any time during the course of the disease, ultimately reducing survival³

Often underappreciated risk factors

- Suboptimal response to therapy¹
 - An uncontrolled hematocrit level
 - Thrombotic events
 - Leukocytosis
 - Thrombocytosis
 - Excessive symptoms or complications
 - Increasing spleen size
- Classic cardiovascular risk factors (eg, diabetes)²

Common challenges in controlling polycythemia vera¹

- Rural patient, no access to a hematologist
- Physician complacency concerning target hematocrit level
- Hematocrit level not monitored closely after diagnosis and not rapidly brought under control
 - Phlebotomy may initially be required frequently, at times every other day
 - The complete blood count should be checked at least every 4 weeks until a steady-state target hematocrit level is achieved
 - Dr Dao's protocol includes initiating phlebotomy immediately to bring the hematocrit level below 45% for men and at 42% for women
 - Many of Dr Dao's patients are resistant to or intolerant of hydroxyurea

Reference: 1. Dao KH. Interview. July 10, 2015. Incyte Corporation. Wilmington, DE.

Case 1: Hydroxyurea failure in an elderly man with depression and an unrelated skin problem¹

- A 79-year-old man with *JAK2V617F* mutation–positive PV was followed for approximately 5 years without any major constitutional symptoms or past thrombotic events
- He was maintained on hydroxyurea 500 mg 3 times daily and with phlebotomy every 4 to 6 weeks to achieve a target hematocrit level of <45%
- He then developed severe palmoplantar psoriasis and his phlebotomy needs escalated to every 3 weeks
- Therapy for the palmoplantar psoriasis led to severe ulcerations and poor wound healing while on hydroxyurea
- A significant depressive episode and his advanced age suggested caution with the use of pegylated interferons

Reference: 1. Dao KH. Interview. July 10, 2015. Incyte Corporation. Wilmington, DE.

Notes on case 1: Hydroxyurea failure in an elderly man with depression and an unrelated skin problem

- Mucocutaneous problems with hydroxyurea can become a serious problem or dose-limiting issue¹
 - Hydroxyurea should be prescribed with caution or stopped altogether in the presence of a preexisting wound or skin ulcer, whether it is from:
 - surgery
 - long-standing diabetes
 - an unrelated treatment
 - Approximately 10% of Dr Dao's patients with PV are not candidates for hydroxyurea because of wounds, including surgery and other ulcerative skin issues¹

In our practice, we are more concerned about the effect of hydroxyurea failure in terms of hematocrit control rather than it being a biomarker for worse disease.¹

Notes on case 1: Hydroxyurea failure in an elderly man with depression and an unrelated skin problem

- Warnings and precautions regarding the use of pegylated interferons include¹:
 - significant depression or other neuropsychiatric disorders
 - history or presence of an autoimmune disease
 - history of significant or unstable cardiac disease
 - retinal disorders
 - hepatic failure

Our facility has also noted that elderly patients are less likely than younger patients to tolerate interferon.²

Case 2: Hydroxyurea failure in a young woman¹

- A 36-year-old woman presented 8 years ago with ascites and liver enzyme abnormalities during elective preoperative work-up
- She was diagnosed with Budd-Chiari syndrome (hepatic vein thrombosis)
- As a result of this complication, often associated with PV, she was tested for the *JAK2V617F* mutation, which came back positive
- She was diagnosed with *JAK2V617F*-positive PV and started on hydroxyurea
- Gastrointestinal upset occurred upon escalation of the dose of hydroxyurea
- Complete blood count revealed erythrocytosis, thrombocytosis, and leukocytosis
- She has been maintained on hydroxyurea while alternating between doses of 1,000 mg daily and 500 mg daily, with phlebotomy every 3 to 4 months
- Her spleen has started to enlarge and phlebotomy requirements have escalated to monthly
- Despite these measures, her hematocrit level remains in the 46% to 48% range

Reference: 1. Dao KH. Interview. July 10, 2015. Incyte Corporation. Wilmington, DE.

The clinical perspectives of Dr Kim-Hien Dao in this presentation are not intended for use as practice guidelines.

Notes on case 2: Hydroxyurea failure in a young woman¹

- High-risk patient with Budd-Chiari syndrome
 - Few symptoms, but the complete blood count every 4 to 6 weeks indicated a need for phlebotomy
 - Phlebotomy still failed to control the hematocrit level to 42%
 - Gastrointestinal upset ruled out escalation of dose of hydroxyurea
 - Trilineage hyperplasia
 - Enlarging spleen, currently monthly phlebotomy

The patient was averse to injections (eliminating interferon) and requested more information on alternative therapy.¹

New risk factors in polycythemia vera¹

- New risk factors may be helpful in communicating prognosis to the patient, but in high-risk disease, the goals of therapy remain the same
- These parameters in isolation would not change Dr Dao's disease management. Besides age >60 and prior thrombosis, other high-risk features exist, including:
 - poor hematocrit control
 - cardiovascular risk factors
 - leukocytosis
 - hydroxyurea failure
 - excessive or escalating symptoms
 - enlarging spleen
 - recurrent thromboses

Reference: 1. Dao KH. Interview. July 10, 2015. Incyte Corporation. Wilmington, DE.

The clinical perspectives of Dr Kim-Hien Dao in this presentation are not intended for use as practice guidelines.

Conclusions

- A subset of patients with PV has aggressive disease with outcomes comparable to those of myelofibrosis^{1,2}
- In my opinion, it is essential for the hematocrit level to be promptly reduced to a sex-appropriate target, with frequent follow-up until the target is reached³
- In rural areas where the patient must be followed by a primary care physician, a hematologist can explicitly communicate the importance and seriousness of strict hematocrit control³
- There is no place for complacency with high-risk patients. Patients who have experienced hydroxyurea failure need alternative therapies to reduce the risk for PV-associated complications³
